

Running simulations using **retrocombinator**

Anindya Sharma

2021-05-27

TODO:

- Give a print message that describes the parameters that have been run in an intuitive fashion
- For each object, have a print function that can do this
- By default, print as a message, but give users the option to dump to a log file
- Search parameter space and label parameters with what scenarios they are likely to lead to

Running Simulations

The **retrocombinator** package provides a method for simulating the molecular evolutionary process of retrotransposon recombination over large scales of time.

To use it, load the library first.

```
library(retrocombinator)
```

To run a simulation, call the `simulateEvolution()` function. This runs a simulation with default parameters.

```
simulateEvolution()  
#> [1] "simulationOutput.out"
```

To overwrite any parameters, first create objects to represent the parameters you wish to overwrite, such as in the example given below. Refer to the section below for what the various parameters are. Whenever a parameter is not specified explicitly, the default will be used.

```
burstParams <- BurstParams(recombMean = 1.0)  
flagParams <- FlagParams(lengthCriticalRegion = 5,  
                          probInactiveWhenMutated = 0.1)  
simulateEvolution(burstParams = burstParams, flagParams = flagParams)  
#> [1] "simulationOutput.out"
```

Using custom sequences

By default, `simulateEvolution()` runs a simulation on randomly generated sequences. To use a custom sequence, specify it in `SequenceParams` (more details in the section below, that describes all possible parameters to the simulation).

```
# --- NOT RUN (this is an alternative) ---  
  
# Obtain your sequence in your favourite way  
library(Biostrings)  
fastaInput <- readDNASTringSet('path/to/your/FASTA/file')  
yourSequence <- toString(fastaInput$yourSequence)  
  
# Override the sequence parameters and pass it to the simulation  
sequenceParams <- SequenceParams(initialSequence = yourSequence)
```

```
simulateEvolution(sequenceParams = sequenceParams)
# -----
```

Simulation parameters and their defaults

- **SequenceParams** represents what set of retrotransposons the simulation starts off with. It is constructed by either specifying an explicit initial sequence, or a sequence length (in which case the sequence is created randomly by sampling from a uniform A/G/C/T distribution.) Besides that, the number of initial copies of the initial retrotransposon needs to be specified (the simulation creates multiple copies of the initial sequence to begin with):
 - **sequenceLength** : **numeric** Sequence length (number of nucleotides) of the initial retrotransposon (constructed randomly); ignored if **initialSequence** is not NULL (**default = 5000**)
 - **initialSequence** : **character** The initial retrotransposon to consider; can be NULL if **sequenceLength** is specified instead (**default = NULL**)
 - **numInitialCopies** : **numeric** Number of copies of initial retrotransposon (**default = 100**)
- **MutationParams** represents how what nucleotide substitution model will be used to modify the sequences during the simulation. It is constructed from one of the following **character** literals to the argument **model**:
 - "JC69" Jules and Cantor - 1969
 - "K80" Kimura - 1980 (**default**)
 - "F81" Felsenstein - 1981
 - "HKY85" Hasegawa, Kishino and Yano - 1985
 - "TN93" Timura and Nei - 1993
 - "GTR" General Time Reversible Model, Tavaré - 1986
- **FlagParams** represents the parameters used during a simulation in which we keep track of a retrotransposon's *active* status. A retrotransposon that is active is capable of transposition or bursting, but potentially loses its active status if a point mutation affects a critical part of the sequence.
 - **lengthCriticalRegion**: **numeric** Sequence length (number of nucleotides) of the critical region of a retrotransposon (**default = 10**)
 - **probInactiveWhenMutated** : **numeric** The probability that a point mutation to the critical region causes a sequence to become inactive (**default = 0.001**)
 - **maxInactiveCopies** : **numeric** The largest population size of inactive sequences to keep track of (if this is exceeded, sequences are randomly discarded to simulate death) (**default = 500**)
- **SimulationParams** represents how long the simulation will run for, and at what timescale. It comprises of the following:
 - **numSteps** : **numeric** The number of steps in our simulation - the simulation starts at a step count of 0, and runs until the step count is **numSteps** (**default = 20**)
 - **timestep** : **numeric** How much real time does one step in our simulation measure, in millions of years (**default = 1**)
 - **maxActiveCopies** : **numeric** The largest population size of active sequences to keep track of (if this is exceeded, sequences are randomly discarded to simulate death) (**default = 500**)
- **BurstParams** represents how an active retrotransposon will burst during transposition. It comprises of the following:
 - **burstProbability** : **numeric** The probability that an active retrotransposon will increase in copy number during a time jump of one timestep (**default = 0.1**)
 - **burstMean** : **numeric** The Poisson mean for the distribution that specifies how many new sequences an active sequence will create during bursting (**default = 1**)
 - **recombMean** : **numeric** The expected number of template switches during recombination between two sequences (chosen from a Poisson distribution with this as its mean) (**default = 1.5**)
 - **recombSimilarity** : **numeric** How similar does an active sequence have to be with another sequence for them to be allowed to be recombine during transposition? (**default = 0.85**)
- **SpeciationParams** represents how we keep track of species during the simulation. It comprises of the following:

- **selectionThreshold** : numeric What sequence similarity to the original sequence do we wish to maintain? Sequences that diverge beyond this similarity level are dropped over the course of simulation (**default = 0.5**)
- **speciesSimilarity** : numeric What sequence similarity do two sequences have to be to each other for them to be considered to be of the same species? (**default = 0.7**)
- **speciesCoherence** : numeric What proportion of the overall sequence similarity matrix of a species needs to score be above **speciesSimilarity** before we decide the species has split into two species? (**default = 0.5**)
- **OutputParams** represents how and where the output of the simulation will be saved. It comprises of the following:
 - **outputFilename** : character Where should the simulation be saved? (**default = 'simulationOutput.out'**)
 - **outputNumRawSequence** : numeric How many times during the event of the simulation should we output the raw sequences (as nucleotide strings) themselves? (**default = 2**)
 - **outputNumInitialDistance** : numeric How many times during the event of the simulation should we output the distance of sequences to the initial sequence? (**default = 10**)
 - **outputNumPairwiseDistance** : numeric How many times during the event of the simulation should we output pairwise distances between all pairs of sequences? (**default = 10**)
 - **outputNumSpeciesTags** : numeric How many times during the event of the simulation should we output the species tags of each of the sequences? (**default = 10**)
- **SeedParams** represents how to select the seed for randomisation for the simulation. It comprises of the following:
 - **toSeed** : logical Should this simulation be run with a specified seed to begin with? If FALSE, a seed based on system time is used (**default = true**)
 - **seedForRandom** : numeric If **toSeed** is TRUE, what should the initial seed for the random number generator be? (**default = 0**)

Output

The simulation creates a custom output file and returns a path to it (specified by **outputFilename** in **OutputParams**, which by default is 'simulationOutput.out'). This file can be parsed by **parseSimulationOutput()**.

```
data <- parseSimulationOutput('simulationOutput.out')
```

```
# --- NOT RUN (this is an alternative) ---
```

```
# Alternatively, using the pipe operator
```

```
library(magrittr) # For %>%
```

```
data <- simulateEvolution() %>%  
  parseSimulationOutput()
```

```
# -----
```

This contains a list of two dataframes, that keep track of retrotransposon sequences, their similarity to the initial sequence, their pairwise similarity, and their lineage, across the timesteps of the evolution.

```
colnames(data$sequences)
```

```
# step - timestep in the simulation
```

```
# realTime - time since the start of the simulation (in millions of years)
```

```
# sequenceId - the unique ID of the sequence (to track it over time)
```

```
# speciesId - the unique ID of a species
```

```
# previousSpeciesId - the unique ID of the species this species emerged from
```

```
# parentMain the unique ID of the sequence this burst from
```

```
# parentOther - the unique ID of the sequence its parent recombined with
```

```

# distanceToInitial - the distance to the initial sequence
# rawSequence - the raw sequence, as a character
# isActive - whether or not the sequence is capable of transposition

colnames(data$pairwise)

# step - timestep in the simulation
# realTime - time since the start of the simulation (in millions of years)
# sequenceId1 - an ID of a sequence present at the time
# sequenceId2 - an ID of a different sequence present at the time
# distancePairwise - the distance between the two sequences

# TODO: colnames(data$params)

```

Analysis

Summary statistics can be obtained from the data as follows.

```

# TODO: summariseEvolution(data)

```

The data can be visualised using the `plotEvolution` function

```

# TODO: plotEvolution(data, "initial") # Distance to initial sequence
# TODO: plotEvolution(data, "pairwise") # Pairwise distances between sequences
# TODO: plotEvolution(data, "phylogeny") # Phylogeny of the sequences

```
